State: Montana
Agency: Fish, Wildlife & Parks
Grant: Montana Shiras Moose Study
Grant number: W-157-R-7
Time period: 1 July, 2018 – 30 June, 2019

Note: All results should be considered preliminary and subject to change; please contact the authors before citing or referencing these data.

Background and summary

Concern has arisen in recent years over widespread declines of North American moose (*Alces alces*) populations along the southern extent of their range. Populations in Montana appear to have declined since the 1990's, as evidenced by aerial survey trends and hunter harvest statistics. While declining populations have clear implications for hunting opportunity, moose management in Montana also suffers from a lack of rigorous data and methods with which to monitor population trends and prescribe actions.

In 2013, Montana Fish, Wildlife, & Parks (MFWP) began a 10-year study designed to improve our understanding of: 1) cost-effective means to monitor statewide moose populations, and 2) the current status and trends of moose populations and the relative importance of factors influencing moose vital rates and limiting population growth (including predators, disease, habitat, and weather). We are using a mechanistic approach to hierarchically assess which factors are drivers of moose vital rates (e.g., adult survival, pregnancy, calf survival), and ultimately influence annual growth of moose populations.

This document is the 7th annual report produced as part of this work. This report contains preliminary results from a subset of our work, including results from the first 6 biological years of moose research and monitoring. All results should be considered preliminary as both data collection and analyses are works in progress.

We continue to explore whether monitoring moose with hunter observations may offer a promising new approach to gathering statewide data. After collecting >4,300 statewide moose sighting locations per year during 2012–2016 through annual hunter phone surveys, we have moved analyses of these data from an occupancy-based (presence-absence) framework into an abundance-based (counts) framework. Results from this work will be finalized during FY20.

Moose vital rates measured with radio-collar studies currently indicate stable to increasing average annual population trends in all 3 study areas (Cabinet-Salish, Big Hole Valley and Rocky Mountain Front). These estimated trends are largely driven by adult female survival rates, which have been variable year by year, but generally have averaged moderate rates of 0.86–0.89 over the full study period. Calf survival appears to have less influence on the overall trajectory of the population but may be important in some areas. For example, calf survival rates are lowest in the Cabinet-Salish population; however, the population appears to remain stable because of high adult female survival. Monitoring of moose vital rates as well as potential limiting factors (predation, disease, and nutrition) will continue for the remainder of this 10-year study.

Location

Moose vital rate research is focused primarily within Beaverhead, Lincoln, Lewis and Clark, Pondera, and Teton counties, Montana. Other portions of monitoring (e.g., genetic and parasite sampling) involve sampling moose from across their statewide distribution.

Study Objectives (2018-2019)

For the 2018-2019 field season of this moose study, the primary objectives were;
   1) Continue to evaluate moose monitoring data and techniques.
   2) Monitor vital rates and limiting factors of moose in three study areas.

Objective #1: *Moose monitoring methods*

1.1. Monitoring moose with sighting rates and patch occupancy modeling

Analyses of animal distribution and abundance that do not require marked animals, such as occupancy models (MacKenzie et al. 2002, 2003) or n-mixture models (Kéry et al. 2018), can effectively use data collected by various means including data collected through citizen science (Hochachka et al. 2012, van Strien et al. 2013). Each year MFWP conducts phone surveys of a large sample of resident deer and elk hunters in Montana to estimate various hunter harvest and effort statistics. Following the 2012–2016 hunting seasons, a subsample of these hunters were also asked to describe the location and group size of any moose sightings that occurred while hunting. These efforts resulted in an average of >4,300 statewide moose sighting locations per year. After completing initial occupancy analyses of the presence-absence of moose across the state (see 2017 Annual Report), we have now moved analyses of these data into a count-based arena. As such, we are using n-mixture models to analyze the numbers of moose seen by hunters while accounting for variation in detection rates. Preliminary results from this work indicate potential to monitor abundance (or relative abundance) at the hunting-district scale (Figure 1).

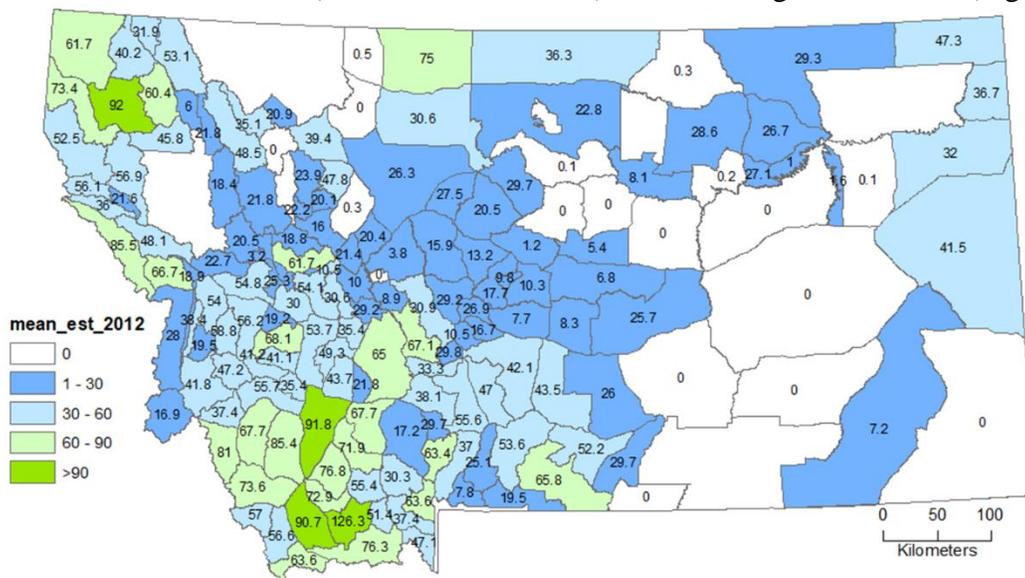

Figure 1. *An example of preliminary spatial predictions of moose abundance from n-mixture modeling of hunter sightings data. This example uses 2012 data only and is very preliminary.*

1.2. Evaluating genetic support for the Shiras subspecies of moose, *A. a. shirasi*

The taxonomic designation of subspecies is often brought to bear in the management and conservation of species, yet the definition and delineation of subspecies units have suffered from inconsistency across taxa and over time. We currently have a manuscript in revision at a peer-reviewed journal that applies a broader lens to the genetic structure of moose in the West. Specifically, we are applying contemporary guidelines of subspecies delineation according to mitochondrial genomics to evaluate the southernmost subspecies of moose, *Alces alces shirasi*. We sequenced the complete mitochondrial genome (*N*=60) as well as 13 nuclear microsatellites (*N*=253) from moose across western North America to evaluate the genetic distinction of moose within the putative range of the *A. a. shirasi* subspecies. Fossil records were consulted to supply phylogeographic context to genetic structure. Results from this study will become available upon acceptance of the manuscript, expected FY20.

Objective #2: *Monitor moose vital rates and potential limiting factors*

**2.1. Animal capture and handling**
In January of 2019 we worked with a contracted helicopter capture company (Quicksilver Air) and local landowners to conduct captures and increase the sample of monitored moose. A total of 24 adult females were captured in 3 study areas in 2018, with the goal of maintaining 30 collared animals in each area. Moose were fit with GPS radio-collars (Lotek LifeCycle and Vectronic Survey Globalstar). During 2013–19, we have conducted a total of 181 captures of 162 individual adult female moose, and as of August 1, 2019, 81 are currently being monitored (Table 1, Figure 2). A target sample size of 30 individuals/study area is sought to achieve moderate precision in annual survival estimates, while minimizing capture and monitoring costs.

Table 1. *Captures of radio-marked adult female moose by study area and year, excluding 6 capture-related mortalities, and the number of adult females being monitored as of August, 2019.*
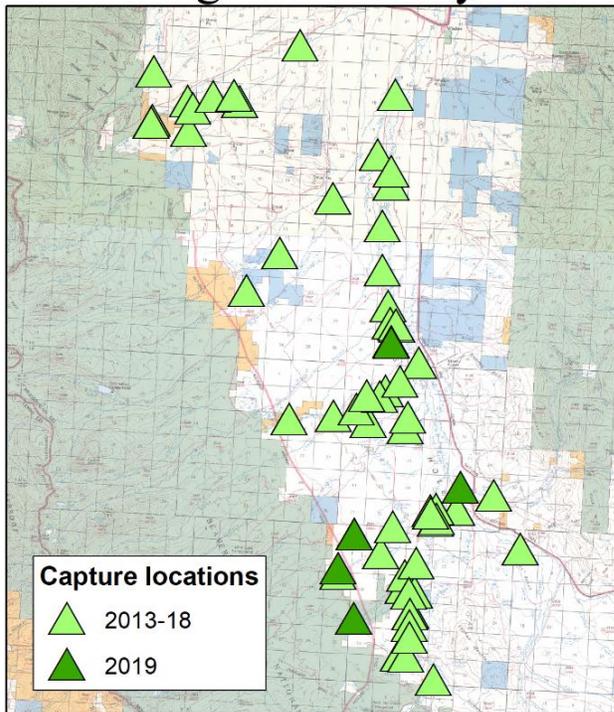

|	Study Area			
	Cabinet-Salish	*Big Hole Valley*	*Rocky Mtn Front*	*Total*
2013 captures	11	12	11	34
2014 captures	7	20	8	35
2015 captures	13	6	7	26
2016 captures	0	4	6	10
2017 captures	10	7	9	26
2018 captures	7	8	11	26
2019 captures	8	6	10	24
Total captures	**56**	**63**	**62**	**181**
Moose currently on–air	24	28	29	81
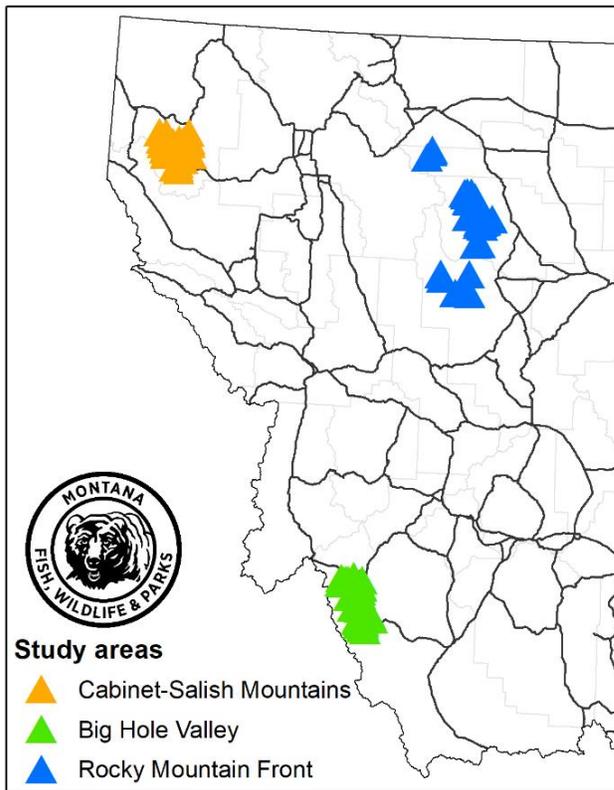

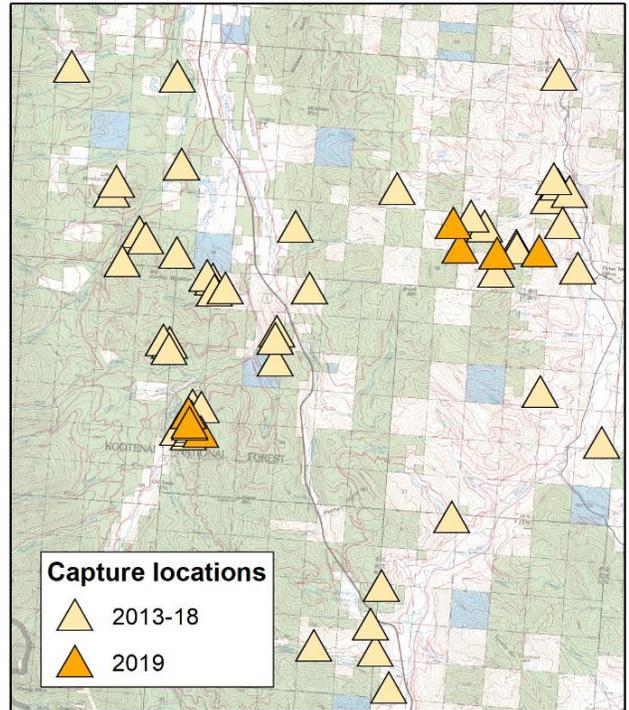

Figure 2. *Moose winter capture locations during 2013–2019 across 3 study areas in Montana.*

2.2. Monitoring vital rates

2.2.1. Adult female survival.— Our study of adult female survival to date includes 141 radio-collared adult female moose and 466 animal-years of monitoring, with a staggered-entry design of individuals entering into the study across 6 winter capture seasons (*see* 2.1 Animal capture and handling). Animals have been deployed with both VHF (*N*=76) and GPS (*N*=86) collars. We estimated Kaplan-Meier annual survival rates for each study area during each biological year as well as across the 5 biological years pooled together in a recurrent-time format.

Pooled annual survival estimates across the entire monitoring period for each study area were 0.891 (SE=0.024, 95% CI=[0.84,0.94]) in the Cabinet-Salish, 0.864 (SE=0.027, 95% CI=[0.81,0.92]) in the Big Hole Valley, and 0.890 (SE=0.025, 95% CI=[0.84,0.94]) on the Rocky Mountain Front (Figure 3). In comparison to these 5-year averages, survival during the 2018-19 biological year was low in the Cabinet-Salish (0.75), higher in the Big Hole Valley (0.93), and low on the Rocky Mountain Front (0.85). While differences among study areas appeared more pronounced during the early years of this study, the mean estimates in each area have gradually grown closer to one another as we continue to accumulate data. These estimates do not account for differences in age distribution of our collared sample, which we will address in more detail upon completion of the study (Prichard et al. 2012).

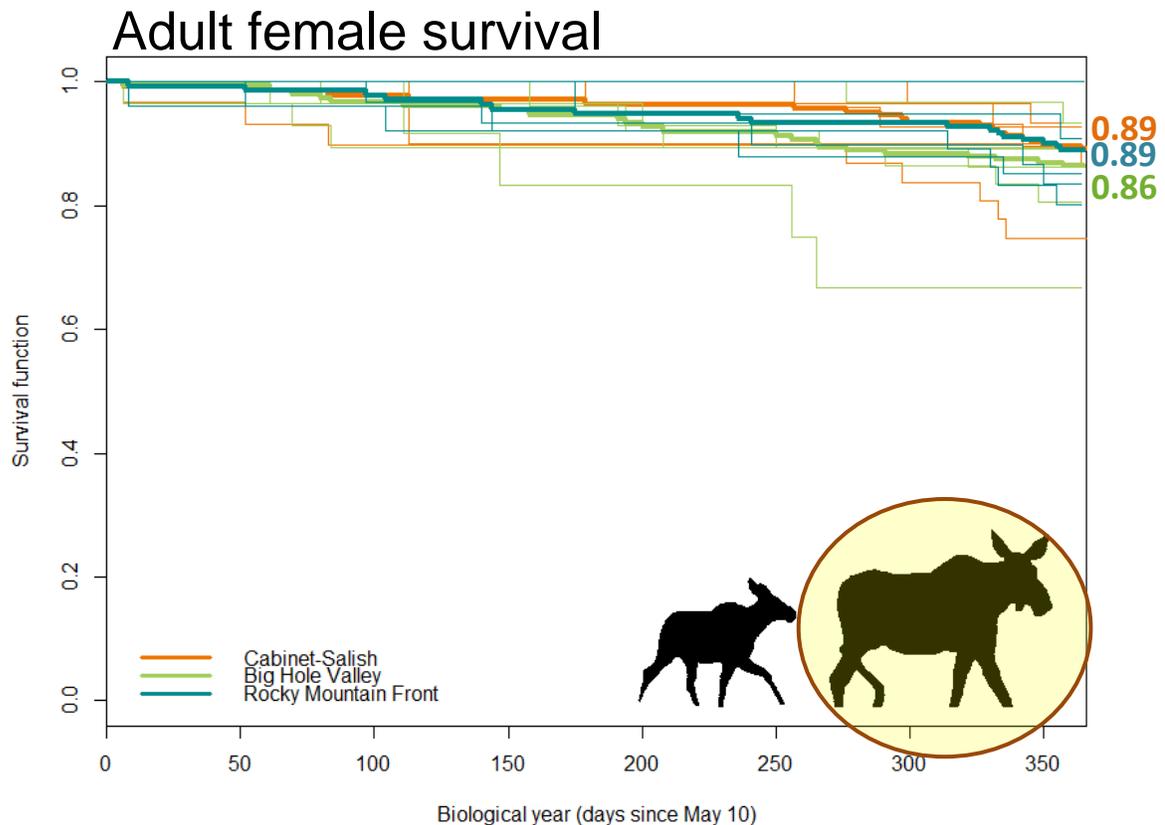

Figure 3. *Kaplan-Meier estimates of annual adult female survival within each study, where bolded lines are pooled estimates across 6 biological years for each study area and thin lines are annual estimates for each study area and year, Montana, 2013–2019.*

During 6 biological years of monitoring, we have documented 58 mortalities of collared adult moose across all study areas: 19 in the Cabinet-Fisher, 22 in the Big Hole Valley and 17 in the Rocky Mountain Front (Table 2, Figure 4). Ongoing research will attempt to better understand the causes and consequences of these mortalities.

Table 2. *Numbers of mortalities by cause for radio-collared adult female moose documented during February 2013–June 2018, Montana.*

Cause of Mortality	Study area		
	Cabinet-Fisher	Big Hole Valley	Rocky Mountain Front
Accident	1	0	0
Health-related (e.g., disease, malnutrition, …)	6	20	8
Human (e.g., harvest, poaching, vehicle collision)	1	2	1
Predation, bear	0	0	1
Predation, mountain lion	1	0	0
Predation, wolf	6	0	2
Predation, wound infection	1	0	0
Unknown	3	0	5

Figure 4. *Example mortality site of F347 in the Big Hole Valley study area, 10 February 2019. This individual was in poor nutritional condition, indicating a chronic health problem potentially related to a parasite load of ≥37 arterial worms in her carotid arteries. No other health-related abnormalities were detected, and she still had a calf with her at the time of death.*

2.2.2 Calf survival.— We decompose calf survival into 2 components: 1) observed parturition rate – the proportion of pregnancies that result in a neonate calf-at-heel during spring; and 2) calf survival – the proportion of documented calves that survive through their first year of life.

    Observed parturition rates: Following winter pregnancy testing, we use weekly aerial telemetry flights during 15 May – 15 July to estimate an "observed parturition" rate, representing the proportion of pregnant cows with neonate calves each spring. One limitation to this approach comes with the unknown proportion of the true number of calves born that die before we visually confirm them. Thus, our sample for subsequent study of calf survival is left truncated (Gilbert et al. 2014), and our Kaplan-Meier based estimates of calf survival should be considered as optimistic to the extent that they don't account for mortality of calves prior to initial detection. Observed parturition rates have been higher in the Big Hole Valley (88%) and Rocky Mountain Front (92%), and lower in the Cabinet-Fisher (76%; Figure 5).   These results are similar to those of other studies (e.g,, Becker 2008) where parturition rates are lower than pregnancy rates due to presumed fetal losses throughout winter and/or death of neonatal calves prior to detection.

    Calf survival: As a result of spring monitoring of neonate calves, we have documented 260 calves from 245 litters during 2013–2017. We then monitored the fates of these calves by visually locating them with their dams throughout their first year of life. Over the first 6 biological years (May 2013 – May 2019), pooled Kaplan-Meier survival estimates of calves-at-heel were 0.366 (SE=0.051, 95% CI=[0.28,0.48]) in the Cabinet-Fisher, 0.445 (SE=0.050, 95% CI=[0.36,0.55]) in the Big Hole Valley, and 0.526 (SE=0.049, 95% CI=[0.44, 0.63]) on the Rocky Mountain Front (Figure 5). Calf survival results mirror those of observed parturition, suggesting observed parturition rates are strongly influenced by mortality of neonates prior to detection, more so than fetal losses.

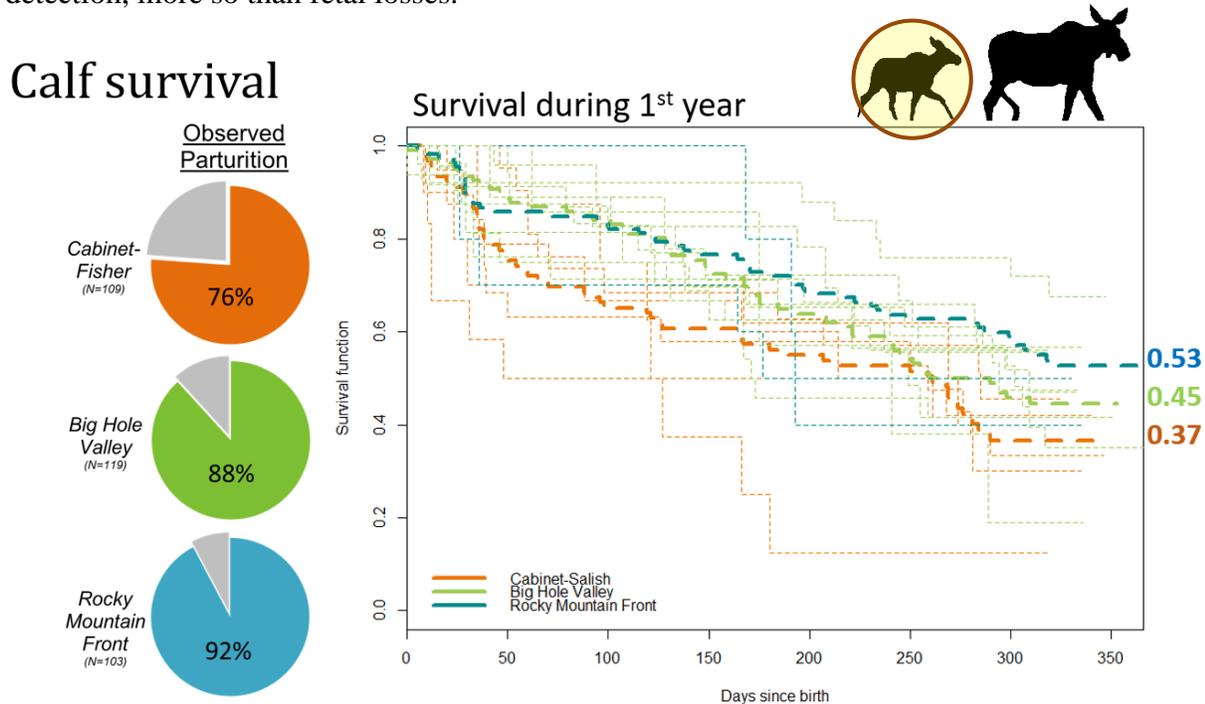

Figure 5. *Observed parturition (proportion of pregnant cows with calves-at-heel during spring) and Kaplan-Meier estimates of annual calf survival for the first year of life within each study area, where bold lines are pooled estimates across 6 biological years and thin lines are annual estimates per year, Montana, 2013–2019.*

2.2.3 Adult female fecundity.—Fecundity for moose is the product of age-specific pregnancy rates and litter size. We monitor pregnancy of animals during winter with laboratory analyses of both blood (serum PSPB levels; Huang et al. 2000) and scat (fecal progestagens; Berger et al. 1999, Murray et al. 2012). To estimate pregnancy in absence of handling animals each winter, we use fecal progestagens from samples collected via ground-tracking.

Pregnancy rates: Pooled across 3 study areas, 6 years (2013-2018), and 417 animal-years of monitoring, the average adult (ages ≥2.5) pregnancy rate was 82%, varying from 81–85% across study areas (Figure 6). Yearling (age 1.5) pregnancy rates appear to vary by region, with 0% pregnancy in both the Cabinet-Fisher and Big Hole Valley study areas compared to 45% yearling pregnancy on the Rocky Mountain Front; however, sample sizes for yearling pregnancy are small ($N = 2$, 7, and 11 in the 3 areas, respectively).

Observed twinning rates: Moose are capable of giving birth to 1–3 calves, though litters are most commonly composed of either 1 or 2 calves (Van Ballenberghe and Ballard 2007). Twinning rates in North American populations can vary from 0 to 90% of births (Gasaway et al. 1992), with variation linked to nutritional condition (Franzmann and Schwartz 1985) and animal age (Ericsson et al. 2001). Twinning rates for Shiras moose are typically low (e.g., <15%; Peek 1962, Schladweiler and Stevens 1973, Becker 2008). Thus far our observed twinning rates are 6% in the Cabinet-Fisher (N=83 litters), 1% in the Big Hole Valley (N=105 litters), and 16% in the Rocky Mountain Front study areas (N=95 litters; Figure 6).

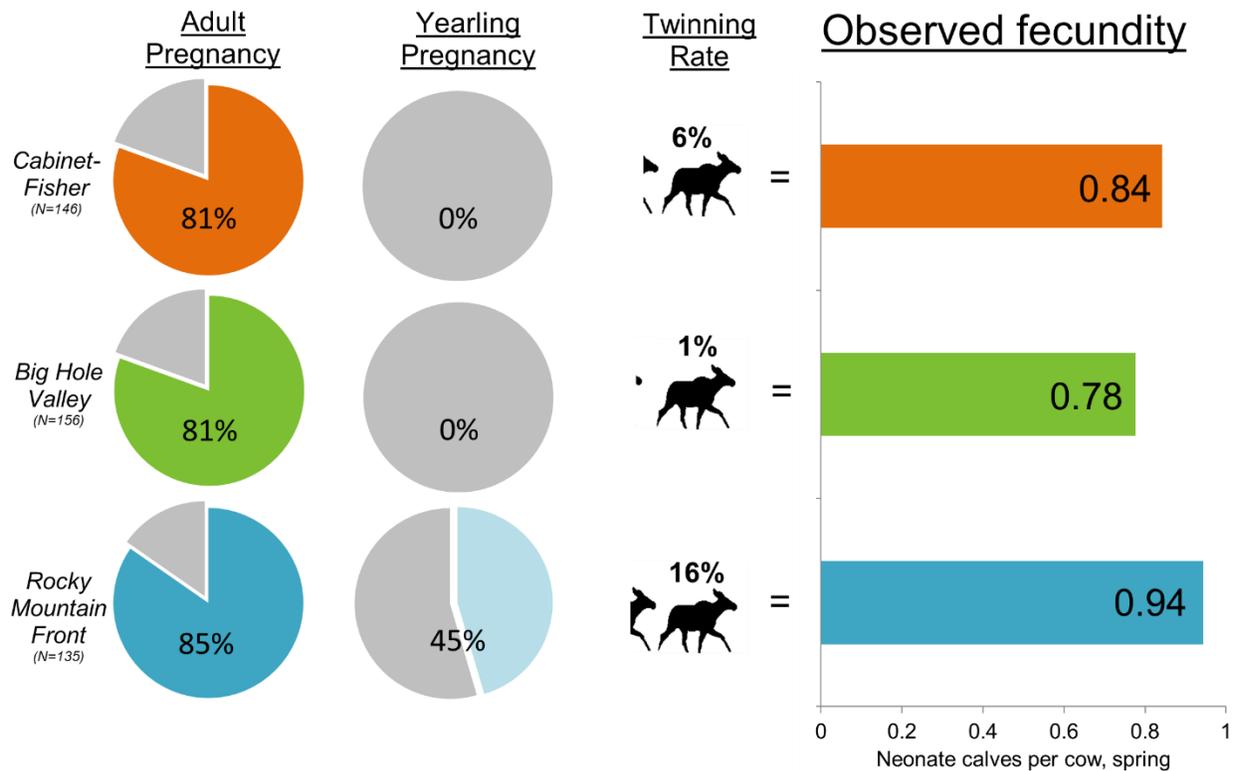

Figure 6. *Estimated adult (age≥2.5) pregnancy rates, yearling (aged 1.5) pregnancy rates, observed twinning rates, and net observed fecundity of calves per adult female in 3 study areas of Montana during 6 biological years, 2013–2018.*

2.2.4. Population growth rates. The overall status of a population may be best characterized by the annual growth rate. This parameter can be estimated by inserting key vital rates into mathematical models, most importantly the annual survival of adult females and the per capita number of calves born and surviving their first year. We estimated recruitment per cow as the integrated product of pregnancy rates, parturition rates, litter size, and calf survival rates. We then estimated annual population growth rates, following DeCesare et al. (2012), for each study population across the first 6 biological years, 2013–2019 (Figure 7).

Given the high elasticity of adult female survival in long-lived, iteroparous species (Eberhardt 2002), adult female survival is the most important vital rate for determining population growth rates. High adult survival, on average, in the Cabinet-Fisher translated to a mean population growth rate of 1.01, or an 1% increase per year, despite consistently seeing the lowest calf survival of all 3 areas. The Rocky Mountain Front moose have seen very high survival rates of both adults and calves as well as high fecundity of adults, resulting in an estimated annual growth rate of 1.12. While vital rates in the Big Hole Valley population were indicative of a declining population for several years, higher adult survival in recent years has increased the overall average to show a stable to increasing population growth rate (1.02) for the first time of the study.

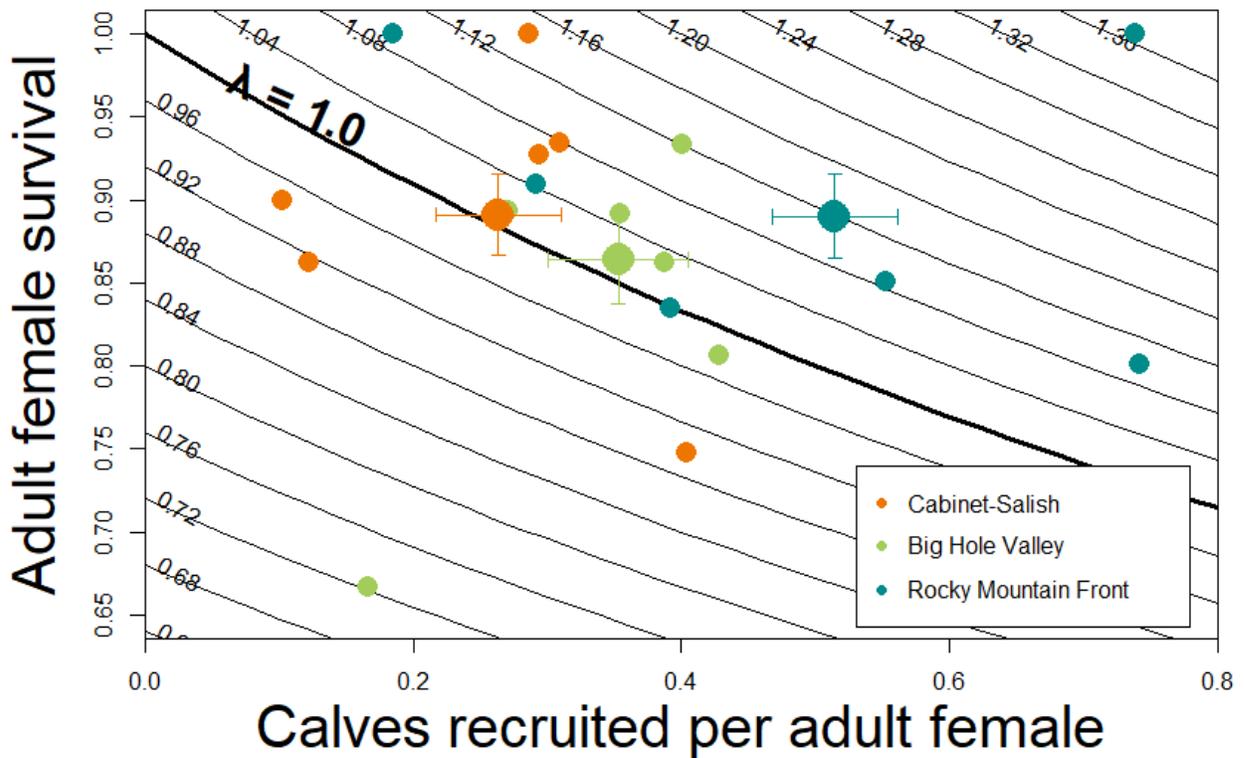

Figure 7. *Contour plot showing the estimated mean annual population growth rates (λ, represented as contour lines) resulting from two-dimensional combinations of adult female survival and spring recruitment of calves (integrating rates of pregnancy, parturition, litter size, and calf survival through the first year). Smaller dots show annual rates for each of 6 biological years, and larger dots and error bars show the pooled averages and standard errors, 2013–2019. Growth rates above the bold line (where λ = 1) indicate a growing population, growth rates below λ = 1 indicate declining populations. Results are preliminary and subject to change.*

2.3. Monitoring nutritional condition, antler spreads, and rutting behavior with the voluntary help of moose hunters

2.3.1. Hunter-based sampling of nutritional condition.
Nutritional condition of ungulates can impact both survival (Roffe et al. 2001, Bender et al. 2008) and fecundity (Testa and Adams 1998, Keech et al. 2000, Testa 2004), and generally provides an indication of the extent to which habitat condition and density dependent effects drive ungulate dynamics (Franzmann and Schwartz 1985, Bertram and Vivion 2002). Rump fat thickness has a strong linear relationship with total body fat in moose (Stephenson et al. 1998). In addition to measuring rump fat among all captured adult females, since 2013 we have asked hunters to measure rump fat of harvested moose.

Moose hunters measured rump fat by marking a toothpick within provided sampling kits for 393 bull and 47 cow moose. Before comparing fat measurements across regions of Montana, we first assessed the relationship between the date each moose was harvested and its respective fat levels, as bull moose are known to lose fat with high energy expenditure during the rutting season (Cederlund et al. 1989). While there was much variation, we found a significant and consistent loss in rump fat depth among bull moose during each of the 5 years ($P<0.001$), whereas fat among cows did not change with day of season ($P=0.68$; Figure 8).

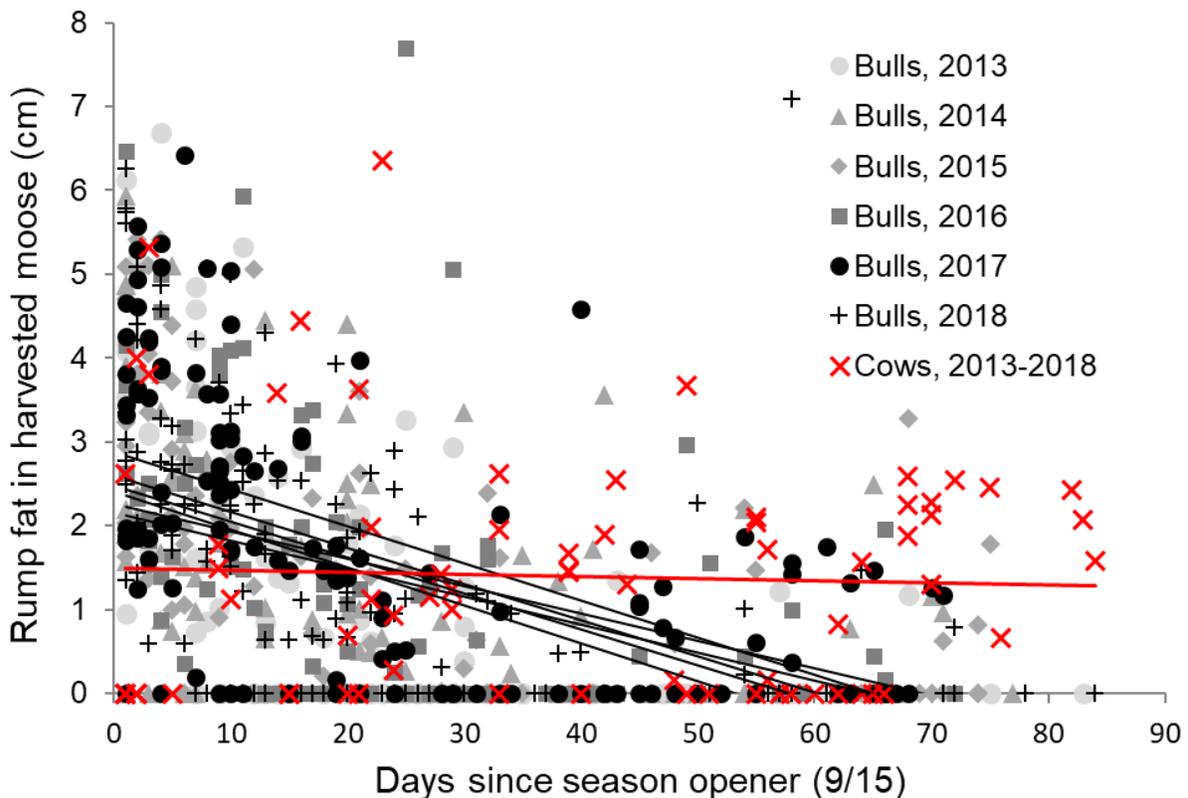

Figure 8. *Depth of rump fat declined consistently among harvested bull moose according to the date of harvest during the past 6 hunting seasons (see 6 black trend-lines), whereas average fat depths among cow moose did not significantly change (red trend-line) during the hunting season, Montana, 2013–2018.*

After assessing how average fat levels changed during the season, we compared observed measurements of fat for each moose to the average expected amount of fat following the trend lines in Figure 8. We then estimated the residuals between observed and predicted values, where a positive value suggested an animal with more fat than expected given the date of harvest, and a negative value an animal with less fat than expected. We compared these residual values among all MFWP regions and found no evidence for statistical differences in the nutritional conditions of bull moose among regions (Figure 9). However, we did find evidence of a difference in the rate at which bulls deplete their fat stores, according to their size (Figure 10). We also found evidence that moose increase in antler spread size up until about the age of 6 years old, at which point antler spreads generally are not affected by age (Figure 11).

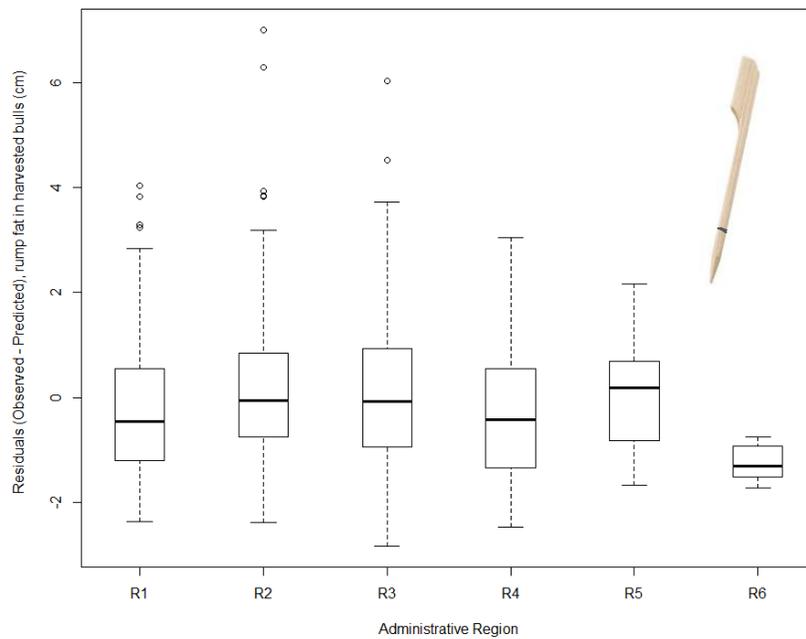

Figure 9. *Average residual values comparing the thickness of rump fat in hunter-killed moose among regions while controlling for the date of harvest. These data were collected by hunters by marking a toothpick (inset photo) included in sampling kits mailed to all license-holders, Montana, 2013–2018.*

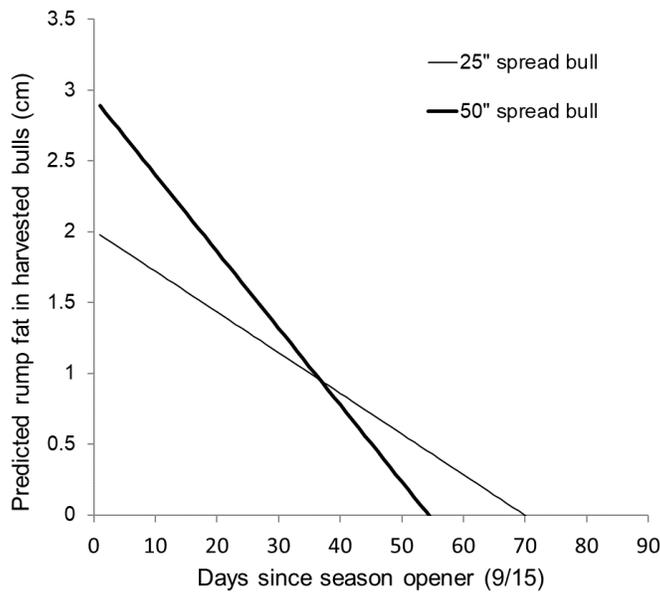

Figure 10. *We also continue to find evidence from hunter-collected measurements of both rump fat and antler spread that larger bulls generally start the rutting season with more fat, but deplete their fat stores at a faster rate than smaller bulls, ending the rut in poorer nutritional condition, Montana, 2013–2018.*
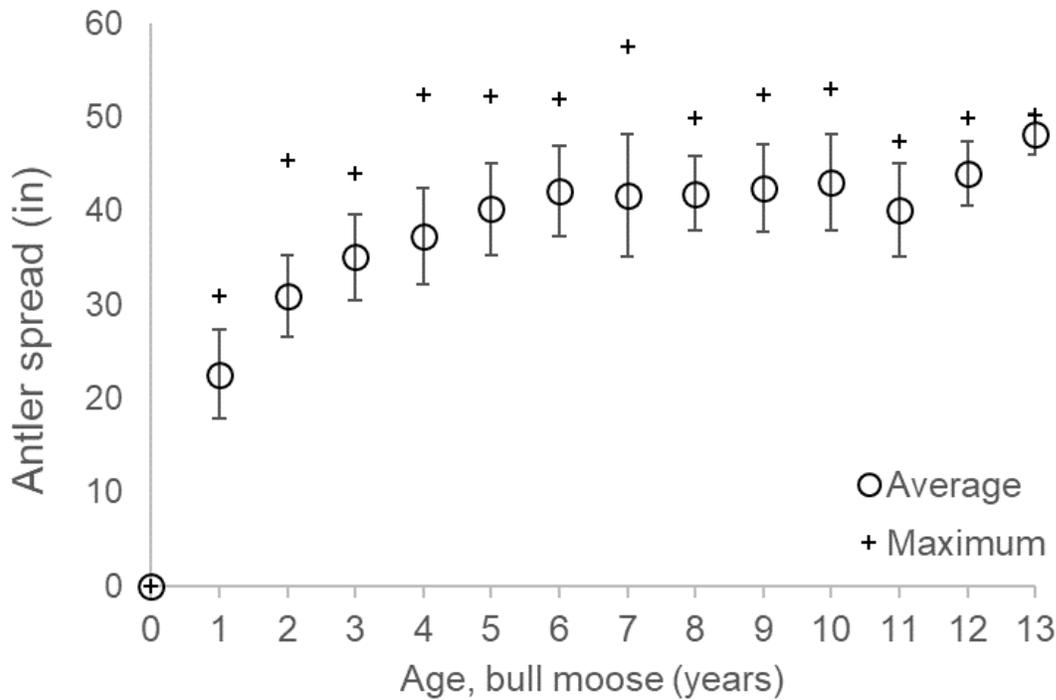

Figure 11. *Hunter self-reported, unofficial, antler spreads (inches) show a gradual increase in the average spread across all moose statewide until about the age of 6, at which point average antler spread holds steady with age.*

2.3.2. Hunter-based monitoring of the rut
For the lucky few (1.2% of applicants in 2018) who draw a moose license each year, one of the first considerations in hunt planning is the timing of the rut for moose in Montana. Mean breeding dates for moose in other studies have included October 5–10 in British Columbia, September 29 in Manitoba, and October 5 in Alaska (Schwartz 2007). During 2016–18, we asked moose hunters to mark on a calendar which days they hunted, and which days they observed rutting activity by moose (e.g., calling, sparring, wallowing). We received samples and/or information from an average of 157 hunters each year, including the recording of 3,632 hunter-days and 555 observations of rutting activity. Hunter-days decreased gradually throughout the season, with recurrent weekly spikes of hunting activity during weekends (Figure 12). To the contrary, the proportion of hunters observing rutting activity increased until the first week of October during both years, after which it declined through the middle of October (Figure 12). These observations are in accordance with our estimates of peak breeding based on estimated average parturition dates for radio-collared cows (May 23rd) and a 231-day gestation (Schwartz & Hundertmark 1993).
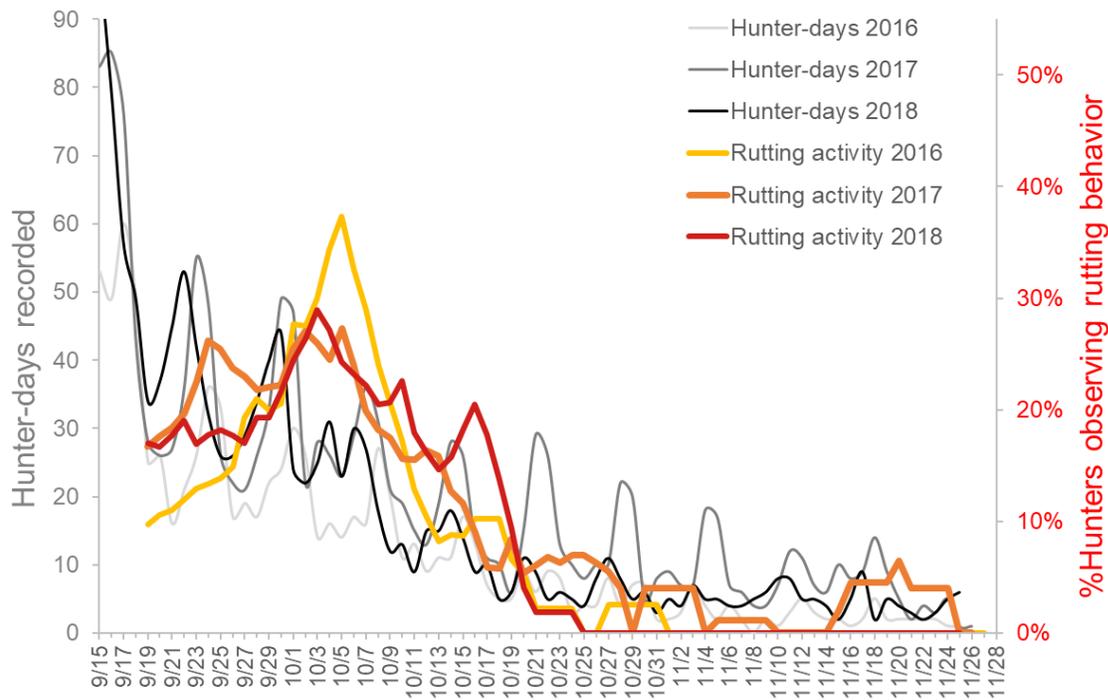

Figure 12. *Hunter-days recorded from voluntary return of data cards and proportion of hunters observing moose rutting activity (using a 5-day moving average) throughout the hunting season, 2016-18, Montana.*
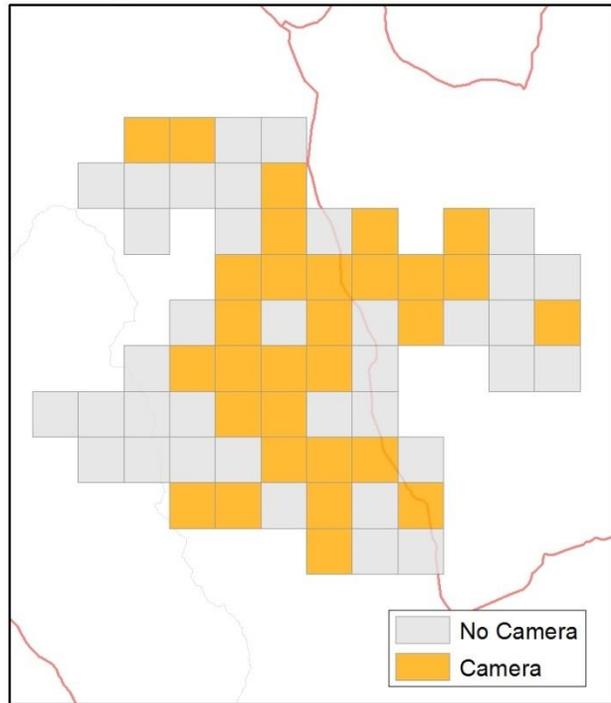

2.4. Multi-species predator occupancy

Predation is among the hypothesized factors potentially limiting moose vital rates in Montana, and the extent to which predation limits moose populations is of widespread interest. Past research has found predation by grizzly bears, black bears and wolves could have potentially significant effects on moose populations, under some circumstances (Messier and Crête 1985, Larsen et al. 1989, Ballard et al. 1990). In addition, mountain lions are known to predate on moose and even coyotes may take calves (Ross and Jalkotzy 1996, Bartnick et al. 2013, Benson and Patterson 2013). Given the potential role of these carnivores in moose population dynamics, and perhaps more importantly the effects of the predator guild as a whole (Sih et al. 1998, Griffin et al. 2011, Keech et al. 2011), we are assessing the relationship between predator densities and moose vital rates. Of particular interest is the effects of predation effects on moose calf survival, which appears to differ between study areas (see pg.8). However, obtaining information on predator populations and their potential to effect moose survival is challenging because these species are cryptic and occur at low densities. Camera trapping is a promising means of obtaining estimates of occupancy and relative density for multiple species simultaneously in a manner that is non-invasive and cost-effective (Rovero & Marshal 2009, Brodie et al. 2014, Steenweg et al. 2016). This has led to rapid expansion of camera trapping for wildlife research and management, and concomitant statistical models to exploit camera data (Meek & Fleming 2014, Burton et al. 2015, Moeller et al. 2018).

Since September 2015 we have continuously operated remote camera grids on 3 moose field study areas to evaluate the ubiety of predators, and the relationship between predator populations and moose vital rates. Remote cameras are deployed year-round in randomly selected cells within the trapping grid (Figure 13). Within the selected cell, unbaited cameras sets are established on trails, closed roads and other travel routes to maximize detection of multiple carnivore species. Local landowners and managers have played an important role in the successful implementation of this research component. Along with providing access to areas, landowners and managers have contributed their knowledge and participation in field work to successfully establish and maintain camera sets. This work continues to foster new and existing relationships with landowners and managers in these areas. As of August 2019, we have deployed remote cameras at 130 sites (43 sites Cabinet-Salish study area; 49 Rocky Mountain Front study area; 38 Big Hole Valley study area) 85 of which are currently active (30 Cabinet-Salish; 28 Rocky Mountain Front; 27 Big Hole Valley). To date we have retrieved and stored images spanning ~85,000 active camera trap-days (35,000 Cabinet-Salish; 25,000 Rocky Mountain Front; and 25,000 Big Hole Valley). Classification of images, including identifying species and enumerating group sizes, is ongoing (Figure 14).

Analytical methods for estimating abundance of unmarked species from observation data is an active area of research (MacKenzie et al. 2002, Royle 2004, Chandler et al. 2013). Accurate estimates of annual abundances of each predator species would be ideal; however, a precise index which detects spatial and temporal heterogeneity in predator abundance/activity would also be useful in assessing the potential influence of predators on moose vital rates (Parsons et al. 2017, Keim et al. 2019). Our camera trapping efforts were designed to use occupancy-based models to estimate probability of occurrence over the study area; as well as extensions of occupancy models which use counts to estimate abundance (Royle 2004, Brodie et al. 2014, Fiske & Chandler 2017). These efforts are also amenable to alternative approaches, such as random encounter and time-to-event models, that also estimate abundance while attempting to account for detection probability (Rowcliffe et al. 2008, Moeller 2017). Additional information to parametrize detection probabilities of grizzly bears and wolves may be incorporated into models based on ongoing GPS telemetry monitoring by collaborators within MT FWP and the U.S. Fish and Wildlife Service.

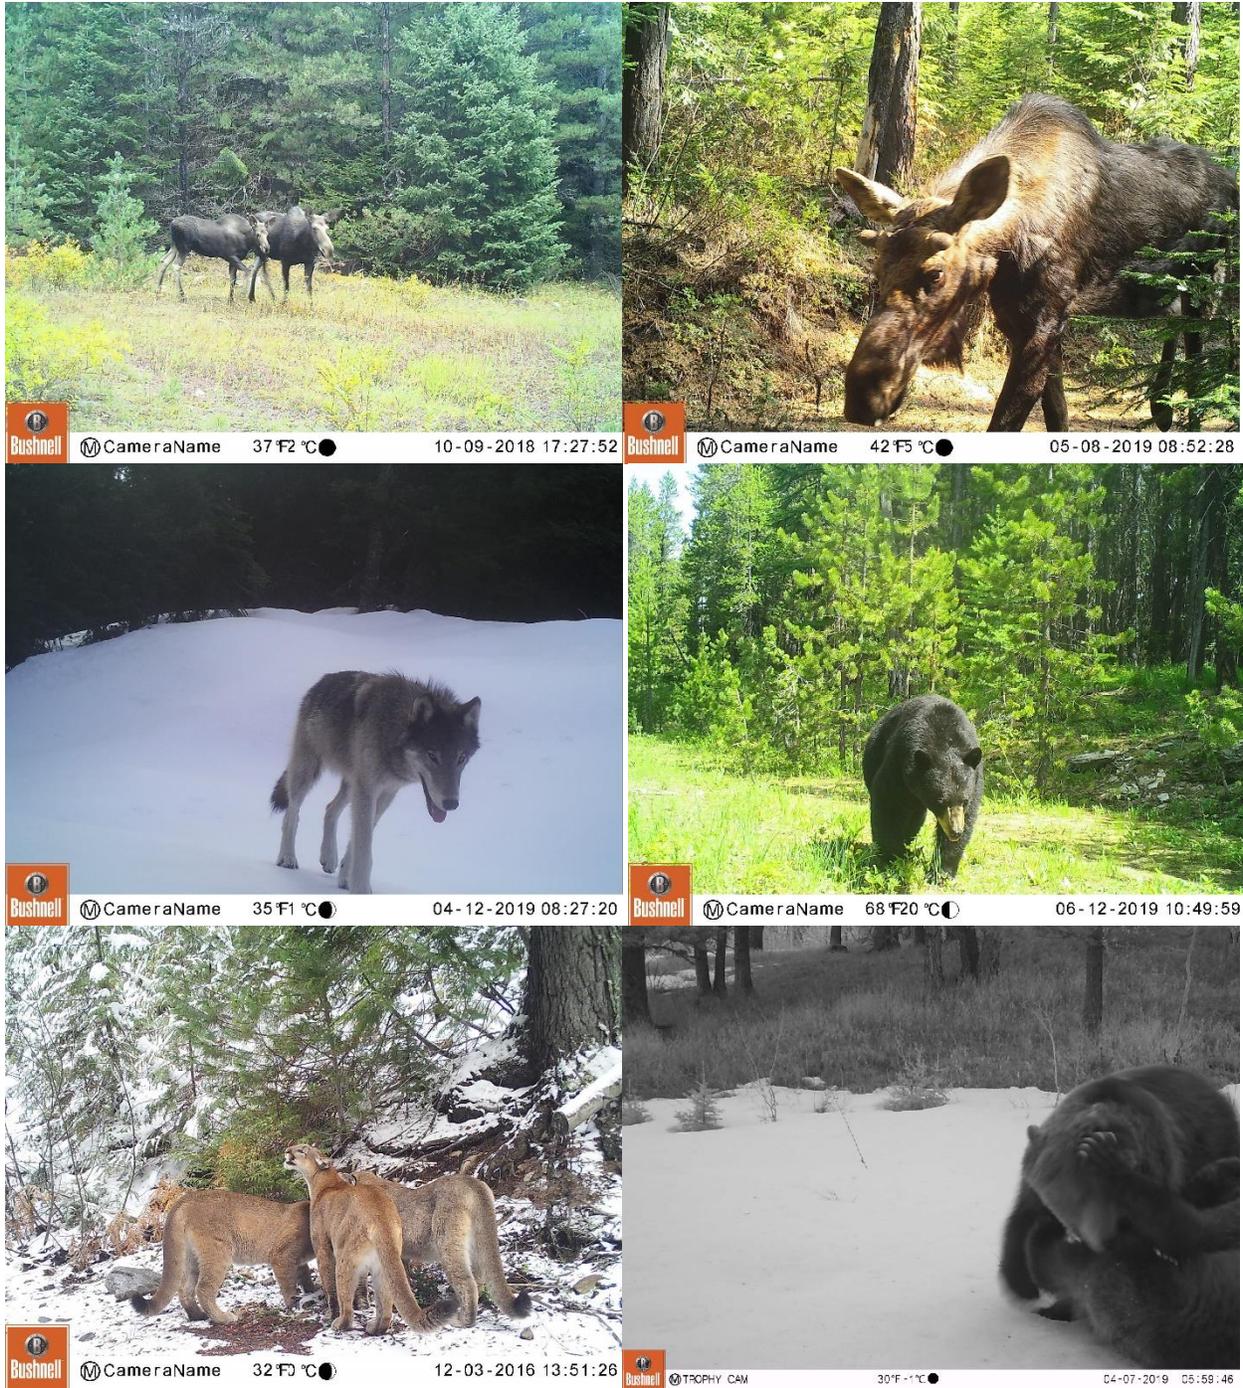

Figure 14. *Example photos from remote camera-traps set within seasonal ranges of each moose study area to monitor multi-species occupancy of carnivores 2015–2019, Montana.*

Deliverables

Below we list project deliverables (publications, reports, presentations, media communications, and value-added collaborations) stemming from this moose research project, during FYs 13–19 (July 2012–June 2019). In addition to those communications listed below, are frequent discussions with moose hunters statewide. Copies of reports and publications are available on the moose study's website (note: the web address is case-sensitive): http://fwp.mt.gov/fishAndWildlife/diseasesAndResearch/research/moose/populationsMonitoring

5. Public and/or Workshop Presentations

FY	Organization (*Speaker*)	Location
2013	Helena Hunters and Anglers Association (*DeCesare*)	Helena, MT
	Marias River Livestock Association (*DeCesare*)	Whitlash, MT
	Plum Creek Timber Company, Staff meeting (*DeCesare*)	Libby, MT
	Sun River Working Group (*DeCesare*)	Augusta, MT

2014	Big Hole Watershed Committee (*DeCesare*)	Divide, MT
	Flathead Wildlife Incorporated (*DeCesare*)	Kalispell, MT
	MFWP R1, Regional Citizens Advisory Council (*Newby*)	Kalispell, MT
	MFWP R1, Biologists' Meeting (*Newby*)	Kalispell, MT
	MFWP R1, Bow Hunter Education Workshop	Kalispell, MT
	MFWP R2, Regional Meeting (*DeCesare*)	Missoula, MT
	MFWP, Wildlife Division Meeting (*DeCesare*)	Fairmont, MT
	Plum Creek Timber Annual Contractors Meeting (*DeCesare*)	Kalispell, MT
	Rocky Mountain Front Land Managers Forum (*DeCesare*)	Choteau, MT
	Swan Ecosystem Center Campfire Program (*Newby*)	Holland Lake, MT
	WCS Community Speaker Series (*Newby*)	Laurin, MT
2015	Big Hole Watershed Committee (*Boccadori*)	Divide, MT
	Flathead Chapter of Society of American Foresters (*Newby*)	Kalispell, MT
	Libby Chapter of Society of American Foresters (*Newby*)	Libby, MT
	MFWP R1, Regional Citizens Advisory Council (*Newby*)	Kalispell, MT
	MFWP R2, Bow Hunter Education Workshop (*DeCesare*)	Lolo, MT
	MFWP R2, Regional Citizens Advisory Council (*DeCesare*)	Missoula, MT
	Rocky Mountain Front Land Managers Forum (*Newby*)	Choteau, MT
	Sanders County Commission Meeting (*DeCesare*)	Thompson Falls, MT
	Sheridan Wildlife Speaker Series (*DeCesare*)	Sheridan, MT
	Univ. Montana Guest Lecture – WILD105 (*DeCesare*)	Missoula, MT
2016	Confederated Salish & Kootenai Tribe, Nat Res Commission (*Newby*)	Marion, MT
	Ducks Unlimited State Convention (*Newby*)	Lewistown, MT
	Helena Hunters and Anglers Association (*DeCesare*)	Helena, MT
	MFWP R1 Law Enforcement Annual Meeting (*Newby*)	Kalispell, MT
	Montana State University, Ecology Seminar Series (*DeCesare*)	Bozeman, MT
	Ravalli County Fish and Wildlife Association (*DeCesare*)	Hamilton, MT
	Univ. Montana Guest Lecture – WILD480 (*DeCesare*)	Missoula, MT
	Upper Sun River Wildlife Team Meeting (*DeCesare*)	August, MT
2017	Big Hole Watershed Committee (*Boccadori*)	Divide, MT
	Mountain Bluebird Trails Conference (*DeCesare*)	Dillon, MT
	Swan Valley Connections Speaker Series (*DeCesare*)	Condon, MT
	University of Montana, STEAMfest (*DeCesare*)	Missoula, MT
	Univ. Montana Guest Lectures – WILD180, WILD480 (*DeCesare*)	Missoula, MT
	WCS Community Speaker Series (*DeCesare*)	Dillon, MT
	Flathead Valley Lions Club (*Newby*)	Kalispell, MT
	Flathead Wildlife Incorporated (*Newby*)	Kalispell, MT
	North Fork Inter-local (*Anderson*)	Polebridge, MT
2018	Bitterroot College (*DeCesare*)	Hamilton, MT
	Clearwater Resource Council (*DeCesare*)	Seeley Lake, MT
	MFWP R1, Regional Citizens Advisory Council (*Newby*)	Kalispell, MT
	Montana Forest Landowner Conference (*DeCesare*)	Helena, MT
	Montana Audubon Chapter (*Newby*)	Polson, MT
	Science on Tap (*Newby*)	Bigfork, MT
2019	MFWP HQ, Brown Bag Seminar (*DeCesare*)	Helena, MT
	MFWP Wildlife Manager Meeting (*DeCesare*)	Helena, MT
	Hellgate Hunters and Anglers (*DeCesare*)	Missoula, MT
	Rocky Mountain Front Land Managers Forum (*Newby*)	Choteau, MT

Upper Sun Wildlife Team (*DeCesare*)		Fairfield, MT
Univ. Montana Guest Lectures – WILD240 (*DeCesare*)		Missoula, MT
Idaho Fish & Game/MFWP Joint Meeting (*Newby*)		De Borgia, MT

7. Other Project-related Collaborations

Partners	Title	Activities during FY18
Rick Gerhold & Caroline Grunenwald, University of Tennessee	Development of a serological assay for *Elaeophora schneideri* detection and surveillance in cervids	*Labwork is ongoing *Providing MT blood samples and worm samples for lab work
Biologists from western states and provinces (AB, BC, CO, ID, MT, OR, SK, UT, WA, WY)	Assessing range-wide genetic differentiation and spatial distribution of a moose subspecies, *Alces alces shirasi*	*Manuscript 2nd revision in review at Journal of Mammalogy
Biologists from western states (CO, ID, MT, OR, UT, WA, WY)	Summarize status and management of western states moose.	*Completed, manuscript published, 2017.
Ky Koitzsch, K2 Consulting, LLC	Estimating population demographics of moose in northern Yellowstone National Park using non-invasive methods	*Field work and analyses completed *Final report in development
Jason Ferrante & Margaret Hunter, USGS – Gainseville, FL	Genetic approaches to understanding moose health	*Analyses ongoing

Acknowledgements

Private landowners & hunters: We are particularly thankful to The Nature Conservancy, Stoltze Land & Lumber, Weyerhaeuser and the many private landowners and area residents who graciously allowed us to conduct captures and ground monitoring on their properties. They also have provided much logistical support and local knowledge about moose distributions and local flora and fauna. We are very grateful for the privilege to work on these properties and for all the help. We are also grateful to the many moose hunters who have given their time and effort to submit samples and information to us as part of their moose hunting experience.

This project is a large collaboration among many FWP biologists. These include but are not limited to Justin Gude, Jennifer Ramsey, Neil Anderson, Keri Carson, Kevin Podruzny, Keri Wash, Jim Williams, Howard Burt, Graham Taylor, Tonya Chilton-Radant, Kent Laudon, John Vore, Vanna Boccadori, Brent Lonner, Gary Olson, Jessy Coltrane, and Ryan Rauscher. Undoubtedly this list should be larger to fully incorporate the many biologists and other personnel who have assisted with coordination of hunter sample collection, harvest statistics,
